PDE and BVP lecture 20

5. Februar 2015 1 / 25

Purpose of Lesson

- To introduce the idea of explicit finite-difference methods and show how they can be used to solve hyperbolic and parabolic problems.
- To show how time-dependent problems can be solved by another finite-difference scheme known as implicit methods.

- We can solve elliptic BVPs (steady-state problems) where the PDE was satisfied in a given region of space, and the solution (or its derivative) was specified on the boundary.
- In those types of problems, we find the approximate solution at the interior grid points by solving a system of algebraic equations. In other words, the solution at all the interior grid points was found simultaneously.

An Explicit Finite-Difference Method

- Now we will show how time-dependent problems can be solved by finite-difference approximations.
- The idea is that if we are given the solution when time is zero, we can then find the solution for $t = \Delta t, 2\Delta t, 3\Delta t, ...$ by means of a marching process.
- Replacing both the space and time derivatives by their finite-difference approximations, we can then solve for the solution u_{i,j} in the difference equation explicitly in terms of the solution at earlier values of time.
- This process is called an explicit-type marching process, since we find the solution at a single value of time in terms of the solution at earlier values of time.

The Explicit Method for Parabolic Equations

- To show how the explicit finite-difference method works, we consider a representative problem from heat flow.
- Heat flows along a rod initially at temperature zero, where the left end of the rod is fixed at temperature one, and the right-hand side experiences a heat loss (or gain) proportional to the difference between the temperature at that end and an outside temperature that is given by g(t).

The Explicit Method for Parabolic Equations (cont.)

Problem 20-1

To find a function u(x, t) that satisfies

PDE:

$$u_t = u_{xx}$$
,
 $0 < x < 1$,
 $0 < t < \infty$

 BCs:
 $u(0, t) = 1$
 $0 < t < \infty$

 IC:
 $u(x, 0) = 0$
 $0 \le x \le 1$

To solve problem 20-1 by finite differnces, we start by drawing the usual rectangular grid system with grid points

$$x_j = jh$$
 $j = 0, 1, 2, ..., n$
 $t_i = ik$ $i = 0, 1, 2, ..., m$

2

- Note that on the figure of the grid system, the u_{i,j} on the left and bottom are given BCs and ICs, and our job is to find the other u_{i,j}'s.
- To do this, we begin by replacing the partial derivatives *u_t* and *u_{xx}* in the heat equation with their approximations

$$u_{t} = \frac{1}{k} [u(x, t+k) - u(x, t)] = \frac{1}{k} (u_{i+1,j} - u_{i,j})$$
$$u_{xx} = \frac{1}{h^{2}} [u(x+h, t) - 2u(x, t) + u(x-h, t)]$$
$$= \frac{1}{h^{2}} (u_{i,j+1} - 2u_{i,j} + u_{i,j-1})$$

 By substituting these approximations into u_t = u_{xx} and solving for the solution at the largest value of time, we have

$$u_{i+1,j} = u_{i,j} + \frac{k}{h^2} \left[u_{i,j+1} - 2u_{i,j} + u_{i,j-1} \right]$$
(20.1)

Remark

(20.1) is the formula we are looking for, since it gives us the solution at one value of time in terms of the solution at earlier values of time.

• We are almost ready to begin the computations for problem 20-1. First, we must approximate the derivatives in the right-hand BC

$$u_x(1,t) = -[u(1,t) - g(t)]$$

by

$$\frac{1}{h} \left[u_{i,n} - u_{i,n-1} \right] = - \left[u_{i,n} - g_i \right], \qquad (20.2)$$

where $g_i = g(ik)$ is given.

- Note that in (20.2) we have replaced u_x(1, t) by the backward-difference approximation, since the forward-difference approximation would require knowing values of u_{i,j} outside the domain.
- Solving (20.2) for $u_{i,n}$ gives us

$$u_{i,n} = \frac{u_{i,n-1} + hg_i}{1+h}.$$
 (20.3)

Algorithm for the Explicit Method

1. Find the solution at the grid points for $t = \Delta t$ by using the explicit formula

$$u_{2,i} = u_{1,i} + \frac{k}{h^2} \left[u_{1,j+1} - 2u_{1,j} + u_{1,j-1} \right]$$
 $j = 2, 3, \dots, n-1$

2. Find $u_{2,n}$ from formula (20.3)

$$u_{2,n} = \frac{u_{2,n-1} + hg_2}{1+h}$$

E 5 4 E

Remark

- Steps 1 and 2 find the solution for $t = \Delta t$.
- To find the solution for $t = 2\Delta t$ repeat steps 1 and 2, moving up one more row (increase *i* by 1) and using the values of $u_{i,j}$ just computed.
- For $t = 3\Delta t, 4\Delta t, \dots$ keep repeating the same process.

On the flow diagram on the next page we explain in a precise manner how the computations should be carried out.

EN 4 EN

Remarks

- There is a serious dificiency in the explicit method, for if the step size in *t* is large compared to the step size in *x*, then machine roundoff error can grow until it ruins the accuracy of the solution.
- The relative size of these steps depends on the particular equation and the BCs, but, generally, the step size in *t* should be much smaller than the step size in *x*. We must have $k/h^2 \le 0.5$ in order this method to work.
- A general rule of thumb is that as the step sizes Δt and Δx are made smaller, the truncation error of approximating partial derivatives by finite differences decreases. However, the smaller these grid sizes, the more computations necessary, and, hence, the roundoff error, as a result of rounding off our computations, will increase.

The Explicit Method for Hyperbolic Equation

Problem 20-2

To find a function u(x, t) that satisfies

PDE: $u_{tt} = u_{xx}$, 0 < x < 1, $0 < t < \infty$ BCs: $\begin{cases} u(0, t) = g_1(t) \\ u(1, t) = g_2(t) \end{cases}$, $0 < t < \infty$ ICs: $\begin{cases} u(x, 0) = \phi(x) \\ u_t(x, 0) = \psi(x) \end{cases}$, $0 \le x \le 1$

© Daria Apushkinskaya (UdS)

< 回 > < 回 > < 回 > -

 Problem 20-2 can also be solved by the explicit finite-difference method. Here, we can approximate the derivatives u_{tt} and u_{xx} by

$$u_{tt} \cong \frac{1}{k^2} [u(x, t+k) - 2u(x, t) + u(x, t-k)]$$
$$u_{xx} \cong \frac{1}{h^2} [u(x+h, t) - 2u(x, t) + u(x-h, t)]$$

and the derivative $u_t(x, 0)$ in the IC by

$$u_t(x,0) \cong \frac{1}{k} [u(x,k) - u(x,0)] = \frac{1}{k} [u(x,k) - \phi(x)].$$

 Solving for u(x, t + k) explicitly in terms of the solution at earlier values of time gives

$$u(x,t+k) = 2u(x,t) - u(x,t-k) + \left(\frac{k}{h}\right)^{2} [u(x+h,t) - 2u(x,t) + u(x-h,t)]$$

 From (20.4) it is clear that we must already know the solution at two previous time steps, and, hence, we must use the initial-velocity condition

$$\frac{1}{k}\left[u(x,k)-\phi(x)\right]=\psi(x)$$

to get us started. Solving for u(x, k) gives $u(x, k) = \phi(x) + k\psi(x)$, and, thus, we can find the solution for $t = \Delta t$.

An Implicit Finite-Difference Method (Crank-Nicolson Method)

- In implicit method, we again replace the partial derivatives in the problem by their finite-difference approximations, but unlike explicit methods (where we solved for $u_{i+1,j}$ explicitly in terms of earlier values), in implicit methods, we solve a system of equations in order to find the solution at the largest value of time.
- In other words, for each new value of time we solve a system of algebraic equations to find all the values.
- It should be mentioned that implicit methods allow us to take larger steps by doing more work per step.

The Heat-Flow Problem Solved by an Implicit Method

Problem 20-3

To find a function u(x, t) that satisfies

PDE: $u_t = u_{xx}$, 0 < x < 1, $0 < t < \infty$ BCs: $\begin{cases} u(0, t) = 0 \\ u(1, t) = 0 \end{cases}$, $0 < t < \infty$ IC: u(x, 0) = 1, $0 \le x \le 1$

Grid system for implicit scheme ($\Delta x=0.2$)

æ

• We replace the partial derivatives u_t and u_{xx} by the following approximations:

$$u_t(x,t) = \frac{1}{k} [u(x,t+k) - u(x,t)]$$

$$u_{xx}(x,t) = \frac{\lambda}{h^2} [u(x+h,t+k) - 2u(x,t+k) + u(x-h,t+k)]$$

$$+ \frac{(1-\lambda)}{h^2} [u(x+h,t) - 2u(x,t) + u(x-h,t)],$$

where λ is a chosen number in the interval [0, 1].

• Note that our approximation for u_{xx} is a weighted average of the central-difference approximation to the derivative u_{xx} at time values t and t + k.

4 3 5 4 3 5 5

Remarks

- In the special case when λ = 0.5, it is just the ordinary average of these two central differences.
- If λ = 0.75, our approximation puts weights of 0.75 and 0.25 on each of the two terms.
- If $\lambda = 0$, it is usual explicit finite-difference method.

If we now substitute the approximations for u_t and u_{xx} into our problem, we get the new finite-difference problem

Problem 20-3a

$$\frac{1}{k} (u_{i+1,j} - u_{i,j}) = \frac{\lambda}{h^2} (u_{i+1,j+1} - 2u_{i+1,j} + u_{i+1,j-1}) \\ + \frac{(1-\lambda)}{h^2} (u_{i,j+1} - 2u_{i,j} + u_{i,j-1})$$
BCs:
$$\begin{cases} u_{i,1} = 0 \\ u_{i,n} = 0 \end{cases} \quad i = 1, 2, \dots, m$$
IC: $u_{1,i} = 1, \qquad j = 2, \dots, n-1$

© Daria Apushkinskaya (UdS)

5. Februar 2015 23 / 25

• If we rewrite the difference equation in problem 20-3a, putting the $u_{i,j}$'s with the largest time subscript (*i*-subscript) on the left-hand side of the equation, we arrive at

$$-\lambda r u_{i+1,j+1} + (1+2r\lambda)u_{i+1,j} - \lambda r u_{i+1,j-1}$$

= $r(1-\lambda)u_{i,j+1} + [1-2r(1-\lambda)]u_{i,j}$ (20.5)
+ $r(1-\lambda)u_{i,j-1}$,

where we have set $r = k/h^2$ for convenience.

- Note that for a fixed subscript *i* and for *j* going from 2 to *n* 1, this is a system of *n* 2 equations in the *n* 2 unknowns *u*_{*i*+1,2}, *u*_{*i*+1,3}, *u*_{*i*+1,4}, ..., *u*_{*i*+1,n-1} [which are the interior grid points at *t* = (*i* + 1)Δ*t*.
- To help show exactly how *u_{i,j}*'s are involved into (20.5), we write it in the symbolic or molecular form (see next page)
