# Computer Algebra and Gröbner Bases 

Frank-Olaf Schreyer

Saarland University WS 2020/21

## Overview

Today's topics are the dimension and integral ring extensions

1. Dimension
2. A Gröbner basis criterion
3. Integral ring extensions
4. Krull's prime existence lemma
5. The lying over theorem

## Definition of the dimension

Definition. Let $A$ be an irreducible algebraic set. Then the dimension of $A$ is

$$
\operatorname{dim} A=\operatorname{trdeg}_{K} K(A)
$$

If $A$ is an algebraic set, then we define

$$
\operatorname{dim} A=\max \left\{\operatorname{dim} A_{i} \mid i=1, \ldots, r\right\}
$$

where $A=A_{1} \cup \ldots \cup A_{r}$ is the decomposition into irreducible algebraic subsets.

## A Gröbner basis criterion

Theorem. Let $I \subset K\left[x_{1}, \ldots, x_{c}, y_{1}, \ldots, y_{d}\right]$ an ideal and $A=V(I) \subset \mathbb{A}^{c+d}$ the corresponding algebraic set. Let $>$ be a global monomial order. Suppose

$$
\operatorname{rad}(\operatorname{Lt}(I))=\left(x_{1}, \ldots, x_{c}\right)
$$

Then $\operatorname{dim} A=d$ and the projection

$$
\pi: A \rightarrow \mathbb{A}^{d}, \quad\left(a_{1}, \ldots, a_{c}, b_{1} \ldots, b_{d}\right) \mapsto\left(b_{1}, \ldots, b_{d}\right)
$$

onto the last $d$ components is surjective.
Moreover, if $\mathrm{Lt}(I)$ is generated by monomials in the subring $K\left[x_{1}, \ldots, x_{c}\right]$, then every associated prime of I defines a variety of dimension d. In particular every irreducible component of $A$ has dimension $d$.

One says that $/$ is unmixed if the conclusion of the additional hypothesis is satisfied.
Corollary. I is unmixed if $\operatorname{Lt}(I)$ is a primary ideal.

## An example

Consider the ideal I generated by the following polynomials of $K\left[x_{0}, \ldots x_{3}\right]$.
With respect to $>_{\text {rlex }}$ the leading terms are the indicated terms, and the calculation shows that the generators are a Gröbner basis.

| $x_{1}^{2}-x_{0} x_{2}$ | $-x_{2}$ | $x_{3}$ |
| :--- | ---: | ---: |
| $x_{1} x_{2}-x_{0} x_{3}$ | $x_{1}$ | $-x_{2}$ |
| $x_{2}^{2}-x_{1} x_{3}$ | $-x_{0}$ | $x_{1}$ |

Thus the assumption of the theorem is satisfied for $x_{1}, x_{2}$ and $y_{1}=x_{0}, y_{2}=x_{3}$. Hence $I$ is unmixed, and every component has dimension 2.

## The tower of projections

Consider the situation of the tower of projections theorem. Theorem. Suppose that $I \subsetneq K\left[x_{1}, \ldots, x_{n}\right]$ is a proper ideal. Let $I_{j}=I \cap K\left[x_{j+1}, \ldots, x_{n}\right]$ be the $j$-th elimination ideal. Set

$$
c=\min \left\{j \mid I_{j}=(0)\right\}
$$

and suppose that for each $j$ with $0 \leq j \leq c-1$ the ideal $l_{j}$ contains an $x_{j+1}$-monic polynomial of degree $d_{j}$. Then the projection $\pi_{c}: V(I) \rightarrow \mathbb{A}^{n-c}$ onto the last $n-c$ components is surjective, and each fiber

$$
\pi_{c}^{-1}\left(a_{c+1}, \ldots, a_{n}\right)
$$

is finite of cardinality $\leq \prod_{j=0}^{c-1} d_{j}$.
Corollary. With the assumption and notation of the tower theorem

$$
\operatorname{dim} V(I)=n-c
$$

holds.

## Proof of the corollary

The assumption of the Gröbner basis criterion is satisfied for $>_{\text {lex }}$ with $d=n-c$ and $y_{1}=x_{c+1}, \ldots, y_{d}=x_{n}$. Indeed $I_{c}=0$ implies

$$
\operatorname{rad}(\operatorname{Lt}(I)) \subset\left(x_{1}, \ldots x_{c}\right)
$$

by the key property of $>_{\text {lex }}$. The existence of the $x_{j}$ monic polynomials in $l_{j-1}$ for $j=1, \ldots, c$ implies that equality holds.

The key concept for the proof of the dimension criterion is the notion of integral ring extensions. This played also the cruicial role in our proof of the Nullstellensatz.

## Integral ring extensions

Definition. Let $R \subset S$ be an inclusion of rings and let $I \subset R$ be an ideal. An element $s \in S$ is integral over $/$ if it satisfies a monic equation

$$
s^{n}+r_{1} s^{n-1}+\ldots+r_{n}=0
$$

with $r_{i} \in I$. s is integral over $R$ if it is integral over the ideal (1) $=R$.
$R \subset S$ is called an integral ring extension if every element $s \in S$
is integral over $R$.
$R \subset S$ is called a finite ring extension if $S$ as an $R$-module is finitely generated.
Example. Let $s \in S$ be integral over $R$. Then $R \subset R[s]$ is a finite ring extension. Indeed, from the monic equation above we see that $R[s]$ is generated by $1, s, \ldots, s^{n-1}$ as an $R$-module.

## Integral elements

Proposition. Let $R \subset S$ be a ring extension and $s \in S$ an element and $I \subset R$ an ideal. TFAE:

1) $s$ is integral over $R$ (over I).
2) $R[s]$ is finite over $R($ and $s \in \operatorname{rad}(I R[s]))$.
3) $R[s]$ is contained in a subring $S^{\prime} \subset S$ which is finite over $R$ (and $s \in \operatorname{rad}\left(I S^{\prime}\right)$ )
Proof. 1) $\Rightarrow 2$ ) was established above. If $s$ is integral over $I$, then the equation says $\left.\left.s^{n} \in I R[s] .2\right) \Rightarrow 3\right)$ is trivially true. 3) $\Rightarrow 1$ ) is the essential direction. Suppose $S^{\prime}$ is generated by $m_{1}, \ldots, m_{n}$ as an $R$-module. Since $s \in \operatorname{rad}\left(I S^{\prime}\right)$ we may write for a suitable power $N$

$$
s^{N} m_{i}=\sum_{j=1}^{n} r_{i j} m_{j}
$$

with $r_{i j} \in I$. In matrix notation we obtain

$$
\left(s^{N} E_{n}-B\right)\left(\begin{array}{c}
m_{1} \\
\vdots \\
m_{n}
\end{array}\right)=0
$$

## Tower of extensions

Multiplying with the cofactor matrix we obtain

$$
\operatorname{det}\left(s^{N} E_{n}-B\right) m_{i}=0
$$

for all $i$. Since $1 \in R \subset S^{\prime}$ is a linear combination of $m_{1}, \ldots, m_{n}$ we obtain

$$
\operatorname{det}\left(s^{N} E_{n}-B\right)=s^{n N}+r_{1} s^{(n-1) N}+\ldots+r_{n}=0
$$

i.e., $s$ is integral over $I$.

Proposition. Let $R \subset S \subset T$ be a tower of finite or integral ring extensions. Then $R \subset T$ is a finite respectively integral ring extension as well.

## Proof

Suppose $s_{1}, \ldots, s_{n}$ generate $S$ as an $R$-module and $t_{1}, \ldots, t_{m}$ generate $T$ as an $S$-module. Then the $n m$ products $s_{i} t_{j}$ generate $T$ as an $R$-module. Every $t \in T$ has an expression $t=\sum a_{j} t_{j}$ with $a_{j} \in S$. Every $a_{j}$ has an expression $a_{j}=\sum r_{i j} s_{i}$. Hence

$$
t=\sum_{i=1}^{n} \sum_{j=1}^{m} r_{i j} s_{i} r_{j}
$$

For the second version consider an element $t \in T$. By assumption $t$ is integral over $S$, i.e., $t$ satisfies an equation

$$
t^{n}+s_{1} t^{n-1}+\ldots+s_{n}=0 \text { with } s_{i} \in S
$$

Since each $s_{i}$ is integral over $R$ the extension

$$
R \subset R\left[s_{1}, \ldots, s_{n}\right]
$$

is finite, hence $R \subset R\left[s_{1}, \ldots, s_{n}, t\right]$ is finite as well and $t$ is integral over $R$ by the conclusion 3) $\Rightarrow 1$ ) above.

## Proof of the dimension criterion

Since $\operatorname{rad}(\operatorname{Lt}(I))=\left(x_{1}, \ldots x_{c}\right)$ we have $I \cap K\left[y_{1}, \ldots, y_{d}\right]=0$. Thus the induced map

$$
K\left[y_{1}, \ldots, y_{d}\right] \rightarrow S=K\left[x_{1}, \ldots x_{c}, y_{1}, \ldots, y_{d}\right] / I
$$

is injective. $K\left[y_{1}, \ldots, y_{d}\right] \subset S$ is a finite ring extension because for each $x_{i}$ there exists an $x_{i}^{n_{i}} \in \operatorname{Lt}(I)$. Hence the $\bar{x}^{\alpha}$ with $\alpha_{i}<n_{i}$ generate $S$ as an $K\left[y_{1}, \ldots, y_{d}\right]$-module by the division theorem. Consider now a minimal primary decomposition

$$
I=\mathfrak{q}_{1} \cap \ldots \cap \mathfrak{q}_{r} .
$$

For at least one associated prime $\mathfrak{p}_{j}=\operatorname{rad}\left(\mathfrak{q}_{j}\right)$ we must have

$$
\mathfrak{p}_{j} \cap K\left[y_{1}, \ldots, y_{d}\right]=0 .
$$

Indeed, if there are non-zero elements $f_{i} \in \mathfrak{p}_{i} \cap K\left[y_{1}, \ldots, y_{d}\right]$ for every $i$, then their product $\prod f_{i} \in \operatorname{rad}(I) \cap K\left[y_{1}, \ldots, y_{d}\right]$ and a suitable power $\left(\Pi f_{i}\right)^{N} \in I \cap K\left[y_{1}, \ldots, y_{d}\right]$ contradicting $\operatorname{Lt}(I) \cap K\left[y_{1}, \ldots, y_{d}\right]=0$.

## Proof of the dimension criterion continued

For $A_{j}=V\left(\mathfrak{p}_{j}\right)$ with $\mathfrak{p}_{j} \cap K\left[y_{1}, \ldots, y_{d}\right]=0$ we have that $K\left[y_{1}, \ldots, y_{d}\right] \subset K\left[A_{j}\right]=K\left[x_{1}, \ldots x_{c}, y_{1}, \ldots, y_{d}\right] / \mathfrak{p}_{j}$ is a finite extension. Hence

$$
K\left(y_{1}, \ldots, y_{d}\right) \subset K\left(A_{j}\right)
$$

is an algebraic field extension and

$$
\operatorname{dim} A_{j}=\operatorname{trdeg}_{K} K\left(A_{j}\right)=\operatorname{trdeg}_{K} K\left(y_{1}, \ldots, y_{d}\right)=d
$$

For $\mathfrak{p}_{i}$ with $\mathfrak{p}_{i}^{c}=\mathfrak{p}_{i} \cap K\left[y_{1}, \ldots, y_{d}\right] \neq 0$ we have for $B_{i}=V\left(\mathfrak{p}_{i}^{c}\right) \subsetneq \mathbb{A}^{d}$ that

$$
K\left[B_{i}\right] \subset K\left[A_{i}\right]
$$

is a finite ring extension and

$$
\operatorname{dim} A_{i}=\operatorname{dim} B_{i}=\operatorname{trdeg}_{K} K\left(B_{i}\right)<d
$$

since $\bar{y}_{1}, \ldots, \bar{y}_{d}$ give algebraic dependent generators of $K\left(B_{i}\right)$ over $K$. Thus

$$
\operatorname{dim} A=\max \left\{\operatorname{dim} A_{j}\right\}=d
$$

## Proof of the unmixedness

In case that $\operatorname{Lt}(I)$ is ( $x_{1}, \ldots, x_{c}$ )-primary $K\left[x_{1}, \ldots x_{c}, y_{1}, \ldots, y_{d}\right] / /$ is actually a free $K\left[y_{1}, \ldots, y_{d}\right]$-module: $\operatorname{Lt}(I)$ is generated by monomials in $K\left[x_{1}, \ldots, x_{c}\right]$ and the monomials $x^{\alpha} \in K\left[x_{1}, \ldots, x_{c}\right] \backslash \operatorname{Lt}(I)$ form a basis by the division theorem. If $\mathfrak{p}_{i}=\operatorname{ann}(m)$ for some $m \in K\left[x_{1}, \ldots x_{c}, y_{1}, \ldots, y_{d}\right] / I$ is an associated prime, then

$$
\mathfrak{p}_{i} \cap K\left[y_{1}, \ldots, y_{d}\right]=\operatorname{ann}_{K\left[y_{1}, \ldots, y_{d}\right]}(m)
$$

is an associated prime of $K\left[x_{1}, \ldots x_{c}, y_{1}, \ldots, y_{d}\right] / I$ as an $K\left[y_{1}, \ldots, y_{d}\right]$-module. But a free module has ( 0 ) as the only associated prime. Thus $\mathfrak{p}_{i} \cap K\left[y_{1}, \ldots, y_{d}\right]=0$ for all $i$ and every associated prime defines a variety $V\left(\mathfrak{p}_{i}\right)$ of dimension $d$.

It remains to prove that the map $\pi: A \rightarrow \mathbb{A}^{d}$ is surjective. We prove a more general result.

## The lying over theorem

Let $R \subset S$ be a ring extension. If $\mathfrak{P}$ is a prime ideal in $S$, then $\mathfrak{p}=\mathfrak{P} \cap R$ is a prime ideal in $R$. One says $\mathfrak{P}$ lies over $\mathfrak{p}$.
Theorem. Let $R \subset S$ be an integral ring extension and let $\mathfrak{p}$ be a prime ideal of $R$. Then:

1) There exists a prime ideal $\mathfrak{P}$ of $S$ with $\mathfrak{p}=\mathfrak{P} \cap R$.
2) There are no strict inclusions between prime ideals lying over p.
3) If $\mathfrak{P}$ is a prime ideal lying over $\mathfrak{p}$, then $\mathfrak{P}$ is a maximal ideal iff $\mathfrak{p}$ is a maximal ideal.
4) If $S$ is noetherian, then the prime ideals lying over $\mathfrak{p}$ are precisely the minimal primes of $\mathfrak{p S}$.

The surjectivity of $\pi: A \rightarrow \mathbb{A}^{d}$ follows from 1) and 3) since maximal ideals in $K\left[x_{1}, \ldots, x_{c}, y_{1}, \ldots y_{d}\right] / I$ corresponds to points $\left(a_{1}, \ldots, a_{c}, b_{1}, \ldots, b_{d}\right) \in A$, and maximal ideals of $K\left[y_{1}, \ldots, y_{d}\right]$ correspond to points $\left(b_{1}, \ldots, b_{d}\right) \in \mathbb{A}^{d}$.

## Krull's prime existence Lemma

Lemma. Let I be an ideal of the ring $R$ and let $U \subset R$ be a multiplicative subset with $I \cap U=\emptyset$. Then there exists a prime ideal $\mathfrak{p}$ of $R$ with $I \subset \mathfrak{p}$ and $U \cap \mathfrak{p}=\emptyset$.
Proof. Consider the set

$$
\mathcal{M}=\{J \subset R \mid J \text { an ideal with } I \subset J \text { and } J \subset U=\emptyset\} .
$$

$\mathcal{M} \neq \emptyset$ because $I \in \mathcal{M}$ and consists of proper ideals because $1 \in U$. Let $\mathfrak{p}$ be a maximal element of $\mathcal{M}$ with respect to inclusion. Then:
Claim. $\mathfrak{p}$ is a prime ideal.
Indeed, suppose $r_{1}, r_{2} \notin \mathfrak{p}$. Then $\left(\mathfrak{p}+\left(r_{j}\right)\right) \cap U \neq \emptyset$ because $\mathfrak{p}$ is maximal in $\mathcal{M}$. Thus there are $a_{j} \in \mathfrak{p}$ such that $a_{j}+r_{j} \in U$. Since $U$ is multiplicative we have

$$
\left(a_{1}+r_{1}\right)\left(a_{2}+r_{2}\right)=\left(a_{1} a_{2}+r_{1} a_{2}+r_{2} a_{1}\right)+r_{1} r_{2} \in U
$$

hence $\mathfrak{p}+\left(r_{1} r_{2}\right) \notin \mathcal{M}$. In particular $r_{1} r_{2} \notin \mathfrak{p}$ as desired.

## Proof of Krull's prime existence lemma continued

The existence of a maximal element $\mathfrak{p}$ in $\mathcal{M}$ is clear if $R$ is noetherian. For more general rings we apply Zorn's Lemma: $\mathcal{M}$ is partially ordered by inclusion. If $\left\{J_{\lambda}\right\}$ is a totally ordered subset set of $\mathcal{M}$, then $\bigcup_{\lambda} J_{\lambda}$ is an upper bound. Thus the assumptions of Zorn's Lemma are satisfied, and $\mathcal{M}$ contains maximal elements.

Corollary. Every proper ideal I in ring $R$ is contained in a maximal ideal.
Proof. We apply Krull's Lemma to $I \subset R$ and $U=\{1\}$.

## Proof of part 1 of the lying over theorem

Consider the ideal $\mathfrak{p S}$ of $S$ and the multiplicative subset $U=R \backslash \mathfrak{p}$ of $S$. Using that $R \subset S$ is integral extension we verify that $\mathfrak{p} S \cap U=\emptyset$ : Every $s \in \mathfrak{p} S$ has an expression $s=\sum_{i=1}^{n} a_{i} s_{i}$ with $a_{i} \in \mathfrak{p}$ and $s_{i} \in S$. Thus $s$ is integral over $\mathfrak{p} R\left[s_{1}, \ldots, s_{n}\right]$. Consider an integral equation

$$
s^{d}+r_{1} s^{d-1}+\ldots+r_{d}=0 \text { with } r_{i} \in \mathfrak{p} .
$$

We have to show that $s \notin U=R \backslash \mathfrak{p}$. Assume the contrary, then $s^{d} \in \mathfrak{p}$, hence $s \in \mathfrak{p}$ since $\mathfrak{p}$ is a prime ideal. This contradicts $s \in U=R \backslash \mathfrak{p}$.
We can now apply Krull's Lemma to the ideal $I=\mathfrak{p} S$ of $S$ and the multiplicative subset $U$. There exists a prime ideal $\mathfrak{P}$ of $S$ with $\mathfrak{p} \subset \mathfrak{p} S \subset \mathfrak{P}$ and $\mathfrak{P} \cap U=\emptyset$. Hence $\mathfrak{P} \cap R \subset \mathfrak{p}$ and equality holds.

## Proof of part 2 of the lying over theorem

Consider prime ideals $\mathfrak{P}_{1} \subset \mathfrak{P}_{2}$ of $S$, both lying over $\mathfrak{p}$. Then $\bar{R}=R / \mathfrak{p} \subset \bar{S}=S / \mathfrak{P}_{1}$ is an integral ring extensions of domains and $\mathfrak{P}_{2} / \mathfrak{P}_{1} \subset \bar{S}$ is a prime ideal which lies over $(0) \subset \bar{R}$. We have to prove that $\mathfrak{P}_{2} / \mathfrak{P}_{1}=(0)$. Suppose $\bar{s} \in \mathfrak{P}_{2} / \mathfrak{P}_{1}$ is non-zero. Let

$$
\bar{s}^{d}+\bar{r}_{1} \bar{s}^{d-1}+\ldots+\bar{r}_{d}=0
$$

be an integral equation of minimal degree. Then $\bar{r}_{d} \in \mathfrak{P}_{2} / \mathfrak{P}_{1} \cap \bar{R}=(0)$. Thus $\bar{r}_{d}=0$. If $d=1$, then this says $s=0$. If $d>1$, then we can divide the integral equation by $\bar{s}$ since $\bar{S}$ is a domain, and we obtain an equation of smaller degree. Thus we get a contradiction in any case.

## Proof of part 3 and 4 of the lying over theorem

3): If $\mathfrak{p}$ is a maximal ideal in $R$, then $\mathfrak{P}$ is a maximal ideal as well by part 2 : Any prime ideal $\mathfrak{P}^{\prime} \supset \mathfrak{P}$ lies over $\mathfrak{p}$ as well because $\mathfrak{p}$ is maximal. Hence $\mathfrak{P}^{\prime}=\mathfrak{P}$ by part 2 .
4): If $\mathfrak{P}$ lies over $\mathfrak{p}$, then $\mathfrak{p} S \subset \mathfrak{P}$ and $\mathfrak{P}$ is a minimal prime containing $\mathfrak{p S}$ by part 2 . Since $S$ is noetherian $\mathfrak{p S}$ has a primary decomposition

$$
\mathfrak{p} S=\mathfrak{Q}_{1} \cap \ldots \cap \mathfrak{Q}_{r}
$$

and $\operatorname{rad}(\mathfrak{p} S)=\mathfrak{P}_{1} \cap \ldots \cap \mathfrak{P}_{r}$ with $\mathfrak{P}_{i}=\operatorname{rad}\left(\mathfrak{Q}_{i}\right)$. Since $\mathfrak{p} S \subset \mathfrak{P}$ implies $\operatorname{rad}(\mathfrak{p} S) \subset \mathfrak{P}$ we conclude that $\mathfrak{P} \supset \mathfrak{P}_{i}$ because otherwise the product of elements $f_{j} \in \mathfrak{P}_{j} \backslash \mathfrak{P}$ would be an element of $\operatorname{rad}(\mathfrak{p} S)$ whose factors do not lie in $\mathfrak{P}$, impossible since $\mathfrak{P}$ is prime. Since $\mathfrak{P}$ is a minimal prime over $\mathfrak{p} S$ we have $\mathfrak{P}=\mathfrak{P}$. Thus $\mathfrak{P}$ coincides with an associated prime of $\mathfrak{p S}$ which is minimal among the associated primes of $\mathfrak{p S}$.

## Algebraic integers

Definition. Let $R \subset L$ be a ring extension. Then the integral closure of $R$ in $L$ is the set

$$
S=\{s \in L \mid s \text { is integral over } R\}
$$

This is a ring because with $s_{1}, s_{2} \in S$ the sum $s_{1}+s_{2} \in R\left[s_{1}, s_{2}\right]$ which is a finite extension of $R$. So $s_{1}+s_{2}$ is integral over $R$ as well. The same argument works for $s_{1} s_{2}$.
The ring of algebraic integers is the integral closure of $\mathbb{Z}$ in $\mathbb{C}$. If $L=\mathbb{Q}\left(a_{1}, \ldots, a_{n}\right)$ is an algebraic number field, then $\mathbb{Z}_{L}$ denotes the integral closure of $\mathbb{Z}$ in $L$. This coincides with the ring of algebraic integers contained in $L$.
By the lying over theorem every non-zero prime ideal $\mathfrak{P} \subset \mathbb{Z}_{L}$ is a maximal ideal, since every prime ideal in $\mathbb{Z}$ is maximal.
If $\mathfrak{P} \subset \mathbb{Z}_{L}$ lies over $(p)$ in $\mathbb{Z}$, then $\mathbb{F}=\mathbb{Z}_{L} / \mathfrak{P}$ is a finite extension field of $\mathbb{F}_{p}=\mathbb{Z} /(p)$.
